

Chapter 3

Control Statements (Part I)

Xuetao Wei

weixt@sustech.edu.cn

Objectives

- ▶ To learn and use basic **problem-solving** techniques
- ▶ To develop **algorithms** using **pseudo codes** (伪代码)
- ▶ To use **if** and **if...else** selection statements (选择/条件语句)
- ▶ To use **while** repetition statement (循环语句)

Programming like a Professional

- ▶ Before writing a program, you should have a thorough understanding of the problem and a carefully planned approach to solving it
- ▶ Understand the types of building blocks that are available and employ proven program-construction techniques

Algorithms (算法)

- ▶ Any computing problem can be solved by executing a series of actions in a specific order
- ▶ An **algorithm** describes a **procedure for solving a problem** in terms of
 - the **actions** to execute and
 - the **order** in which these actions execute
- ▶ The “rise-and-shine algorithm” for a typical white-collar worker: (1) get out of bed; (2) take off pajamas; (3) take a shower; (4) get dressed; (5) eat breakfast; (6) drive to work.
- ▶ Specifying the order in which statements (actions) execute in a program is called **program control**.

Pseudocode (伪代码)

- ▶ **Pseudocode** is an informal language for developing algorithms
- ▶ Similar to everyday English
- ▶ Helps you “think out” a program
- ▶ Pseudocode normally describes only statements representing the actions, e.g., input, output or calculations.
- ▶ Carefully prepared pseudocode can be easily converted to a corresponding Java program

```
Start Program  
Enter two numbers, A, B  
Add the numbers together  
Print Sum  
End Program
```

Control Structures

- ▶ **Sequential execution (顺序执行)**: normally, statements in a program are executed one after the other in the order in which they are written.
- ▶ **Transfer of control (控制跳转)**: various Java statements enable you to specify the next statement to execute, which is not necessarily the next one in sequence.
- ▶ All programs can be written in terms of only three control structures—the **sequence structure**, the **selection structure** and the **repetition structure** (顺序, 选择, 循环)

Sequence Structure (顺序)

- ▶ Unless directed otherwise, computers execute Java statements one after the other in the order in which they're written.
- ▶ The **activity diagram** (a flowchart showing activities performed by a system) in **UML** (**U**nified **M**odeling **L**anguage, 统一建模语言) below illustrates a typical sequence structure in which two calculations are performed in order.

Selection Structure (选择)

- ▶ Three types of selection statements:
 - if statement
 - if...else statement
 - switch statement

Repetition Structure (循环)

- ▶ Three **repetition statements** (a.k.a., **looping statements**).
Perform statements repeatedly while a **loop-continuation condition** remains true.
 - **while** statement
 - **for** statement
 - **do...while** statement

if Single-Selection Statement

- ▶ Pseudocode:

If student's grade is greater than or equal to 60

Print "Passed"

Only one choice, so it is called "single-selection"

- ▶ Java code:

```
if ( studentGrade >= 60 )  
    System.out.println( "Passed" );
```

if Single-Selection Statement

Activity diagram in UML
(Unified Modeling Language
统一建模语言)

- ▶ Diamond, or **decision symbol**, indicates that a decision is to be made.
- ▶ Workflow continues along a path determined by the symbol's **guard conditions** (约束条件), which can be **true** or **false**.
- ▶ Each transition arrow from a decision symbol has a guard condition.
- ▶ If a guard condition is **true**, the workflow enters the action state to which the transition arrow points.

if...else Double-Selection Statement

- ▶ Pseudocode:

If student's grade is greater than or equal to 60

Print "Passed"

Else

Print "Failed"

Two choices, so it is called
"double-selection"

- ▶ Java code:

```
if ( grade >= 60 )  
    System.out.println( "Passed" );  
else  
    System.out.println( "Failed" );
```

if...else Double-Selection Statement

- ▶ The symbols in the UML activity diagram represent actions and decisions

Conditional operator ?:

```
String result = studentGrade >= 60 (?) "Passed" : "Failed"
```

The operands ? and : form a conditional expression.

Shorthand of if...else

Conditional operator ?:

```
String result = studentGrade >= 60 ? "Passed" : "Failed"
```

A **boolean expression** that evaluates to true or false

The conditional expression takes this value if the boolean expression evaluates to true

The conditional expression takes this value if the boolean expression evaluates to false

Equivalent to

```
String result;  
if ( studentGrade >= 60 )  
    result = "Passed";  
else  
    result = "Failed";
```

A More Complex Example

► Pseudocode:

If student's grade is greater than or equal to 90

Print "A"

else

If student's grade is greater than or equal to 80

Print "B"

else

If student's grade is greater than or equal to 70

Print "C"

else

If student's grade is greater than or equal to 60

Print "D"

else

Print "F"

Nested if...else statements (嵌套)

A More Complex Example

- Translate the pseudocode to real Java code:

```
if ( studentGrade >= 90 )
    System.out.println( "A" );
else
    if ( studentGrade >= 80 )
        System.out.println( "B" );
    else
        if ( studentGrade >= 70 )
            System.out.println( "C" );
        else
            if ( studentGrade >= 60 )
                System.out.println( "D" );
            else
                System.out.println( "F" );
```

A More Elegant Version

- ▶ Most Java programmers prefer to write the preceding nested if...else statement as:

```
if ( studentGrade >= 90 )  
    System.out.println( "A" );  
else if ( studentGrade >= 80 )  
    System.out.println( "B" );  
else if ( studentGrade >= 70 )  
    System.out.println( "C" );  
else if ( studentGrade >= 60 )  
    System.out.println( "D" );  
else  
    System.out.println( "F" );
```

If-else Matching Rule

- ▶ The Java compiler always associates an `else` with the immediately preceding `if` unless told to do otherwise by the placement of braces (`{` and `}`)
- ▶ The following code does not execute like what it appears:

```
if ( x > 5 )
```

```
    if ( y > 5 )
```

```
        System.out.println( "x and y are > 5" );
```

```
else
```

```
    System.out.println( "x is <= 5" );
```

If-else Matching Rule

- ▶ Extra spaces are irrelevant in Java (only for formatting). The compiler actually interprets the statement as

```
if ( x > 5 )  
    if ( y > 5 )  
        System.out.println( "x and y are > 5" );  
    else  
        System.out.println( "x is <= 5" );
```

If-else Matching Rule

What if you really want this effect?

```
if ( x > 5 )  
    if ( y > 5 )  
        System.out.println( "x and y are > 5" );  
else  
    System.out.println( "x is <= 5" );
```

```
if ( x > 5 ) {  
    if ( y > 5 )  
        System.out.println( "x and y are > 5" );  
} else  
    System.out.println( "x is <= 5" );
```

Curly braces indicate that the 2nd if is the body of the 1st if

Tip: always use {} to make the bodies of if and else clear.

Empty Statement

- ▶ Just as a block (代码块) can be placed anywhere a single statement can be placed, it's also possible to have an empty statement (空语句)
- ▶ The empty statement is represented by placing a semicolon (;) where a statement would normally be

```
if (x == 1) {  
    ;  
} else if (x == 2) {  
    ;  
} else {  
    ;  
}
```

```
if (x == 1); {  
    System.out.print("I always execute");  
}
```

The two programs are valid, although not quite meaningful.

while Repetition Statement

- ▶ Repeat an action while a condition remains true
- ▶ Pseudocode

While there are more items on my shopping list

Purchase next item and cross it off my list

- ▶ The repetition statement's body may be a single statement or a block. Eventually, the condition should become false, and the repetition terminates, and the first statement after the repetition statement executes (otherwise, **endless loop** 死循环).

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
while ( product <= 100 ) {  
    product = 3 * product;  
}  
// other statements
```

The body of the while loop

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
→ int product = 3;

   while ( product <= 100 ) {
       product = 3 * product;
   }

   // other statements
```

product value

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
→ while ( product <= 100 ) {  
    product = 3 * product;  
}  
// other statements
```

product value
3

Condition true
Enter loop body

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
while ( product <= 100 ) {  
→   product = 3 * product;  
}  
// other statements
```

product value
3
9

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
→ while ( product <= 100 ) {  
    product = 3 * product;  
}  
// other statements
```

product value
3
9

Condition true
Enter loop body

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;
while ( product <= 100 ) {
    → product = 3 * product;
}
// other statements
```

product value
3
9
27

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
→ while ( product <= 100 ) {  
    product = 3 * product;  
}  
// other statements
```

product value
3
9
27

Condition true
Enter loop body

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
while ( product <= 100 ) {  
→   product = 3 * product;  
}  
// other statements
```

product value
3
9
27
81

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
→ while ( product <= 100 ) {  
    product = 3 * product;  
}  
// other statements
```

product value
3
9
27
81

Condition true
Enter loop body

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;
while ( product <= 100 ) {
    → product = 3 * product;
}
// other statements
```

product value
3
9
27
81
243

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
→ while ( product <= 100 ) {  
    product = 3 * product;  
}  
// other statements
```

product value
3
9
27
81
243

Condition false
Exit loop

Example

- ▶ Example of Java's `while` repetition statement: find the first power of 3 larger than 100

```
int product = 3;  
while ( product <= 100 ) {  
    product = 3 * product;  
}
```

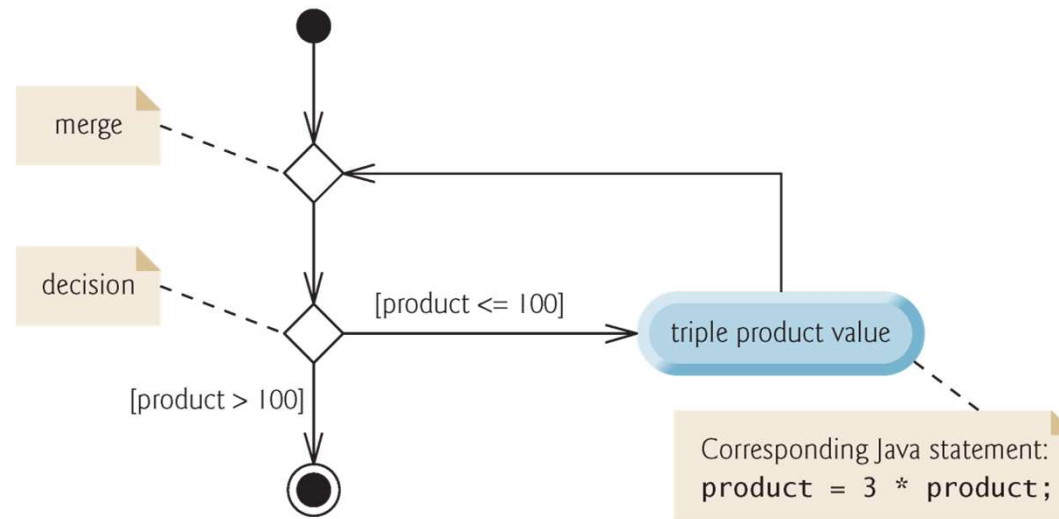

→ // other statements

The first statement after the while
statement will be executed

product value
3
9
27
81
243

while Statement Activity Diagram

- ▶ The UML represents both the **merge symbol** and the decision symbol as diamonds
- ▶ The merge symbol joins two flows of activity into one

Will This Program Terminate?

(下面程序的循环会终止吗?)

```
int product = 3;
while ( product <= 100 ) {
    int x = 3 * product;
}
// other statements
```

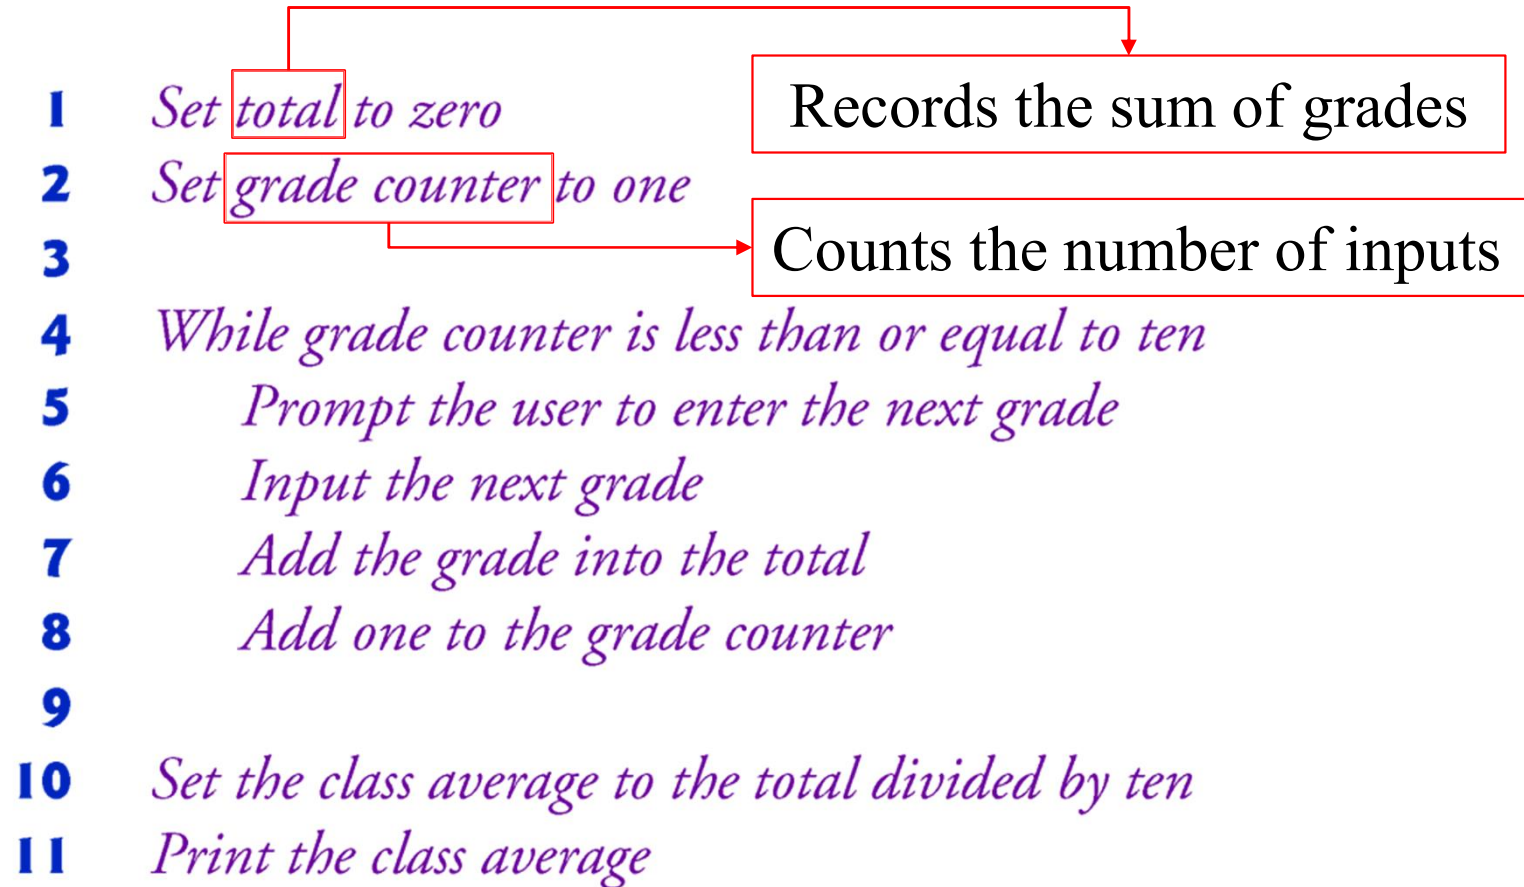

Formulating Algorithms

Counter-Controlled Repetition

(计数器控制的循环)

- ▶ **Class-Average Problem:** *A class of ten students took a quiz. The grades (integers in the range 0 to 100) for this quiz are available to you. Determine the class average on the quiz*
- ▶ **Analysis:** The algorithm for solving this problem on a computer must input each grade, keep track of the total of all grades input, perform the averaging calculation and print the result
- ▶ **Solution:** Use counter-controlled repetition to input the grades one at a time. A variable called a counter (or control variable) controls the number of times a set of statements will execute.

The Pseudo Code

Translate to Java Code

```
// Counter-controlled repetition: Class-average problem
import java.util.Scanner;
public class ClassAverage {

    public static void main(String[] args) {

        // create Scanner to obtain input from command window
        Scanner input = new Scanner(System.in);

        int total; // sum of grades entered by user
        int gradeCounter; // number of the grade to be entered next
        int grade; // grade value entered by user
        int average; // average of grades

        // initialization phase
        total = 0; // initialize total
        gradeCounter = 1; // initialize loop counter
```

Translate to Java Code

```
// processing phase
while(gradeCounter <= 10) { // loop 10 times
    System.out.print("Enter grade: "); // prompt
    grade = input.nextInt(); // input next grade
    total = total + grade; // add grade to total
    gradeCounter = gradeCounter + 1; // increment counter by 1
} // end while

// termination phase
average = total / 10; // integer division yields integer result

// display total and average of grades
System.out.printf("\nTotal of all 10 grades is %d\n", total);
System.out.printf("Class average is %d\n", average);

// close Scanner to avoid resource leak
input.close();
} // end main
} // end class ClassAverage
```

A Sample Run

```
Enter grade: 67
Enter grade: 78
Enter grade: 89
Enter grade: 67
Enter grade: 87
Enter grade: 98
Enter grade: 93
Enter grade: 85
Enter grade: 82
Enter grade: 100
```

```
Total of all 10 grades is 846
Class average is 84
```

Sentinel-Controlled Repetition

(边界值控制的循环)

- ▶ ***A new class-average problem:*** *Develop a program that processes grades for an arbitrary number of students and output the average grade.*
- ▶ **Analysis:** In the earlier problem, the number of students was known in advance, but here how can the program determine when to stop the input of grades?

Sentinel-Controlled Repetition

We can use **a special value** called a **sentinel value** can be used to indicate “end of data entry”.

Marking the end of inputs

92, 77, 68, 84, 35, 72, 95, 79, 88, 84, **-1**

Sentinel-Controlled Repetition

- ▶ Sentinel-controlled repetition is often called **indefinite repetition** (不确定循环) because the number of repetitions is not known before the loop begins executing
- ▶ A sentinel value must be chosen that cannot be confused with an acceptable input value

One of the left items? Of course not...

Pseudo Code

1 *Initialize total to zero* *total* stores the sum of grades
2 *Initialize counter to zero* *counter* stores the number grades

3
4 *Prompt the user to enter the first grade*
5 *Input the first grade (possibly the sentinel)* Try to take an input

6
7 *While the user has not yet entered the sentinel*
8 *Add this grade into the running total*
9 *Add one to the grade counter* If no sentinel value seen,
10 *Prompt the user to enter the next grade* repeat the process
11 *Input the next grade (possibly the sentinel)*

12
13 *If the counter is not equal to zero*
14 *Set the average to the total divided by the counter*
15 *Print the average* Compute and print average
16 *else* (avoid division by 0)
17 *Print "No grades were entered"*

Java Code

```
// Sentinel-controlled repetition: Class-average problem
import java.util.Scanner;
public class ClassAverage2 {
    public static void main(String[] args) {
        // create Scanner to obtain input from command window
        Scanner input = new Scanner(System.in);

        int total; // sum of grades
        int gradeCounter; // number of grades entered
        int grade; // grade value
        double average; // number with decimal point for average

        // initialization phase
        total = 0; // initialize total
        gradeCounter = 0; // initialize loop counter

        // processing phase
        // prompt for input and read grade from user
        System.out.print("Enter grade or -1 to quit: ");
        grade = input.nextInt();
```

Sentinel value

```
// loop until sentinel value read from user
while (grade != -1) {
    total = total + grade; // add grade to total
    gradeCounter = gradeCounter + 1; // increment counter
    // prompt for input and read next grade from user
    System.out.print("Enter grade or -1 to quit: ");
    grade = input.nextInt();
} // end while

// termination phase
if (gradeCounter != 0) { // if user entered at least one grade
    // calculate average of all grades entered
    average = (double) total / gradeCounter;
    // display total and average (with two digits of precision)
    System.out.printf("\nTotal of the %d grades entered is %d\n",
        gradeCounter, total);
    System.out.printf("Class average is %.2f\n", average);
} else { // no grades were entered, output appropriate message
    System.out.println("No grades were entered");
} // end if
```

```
// close Scanner to avoid resource leak
input.close();
} // end main
} // end class ClassAverage2
```

```
Enter grade or -1 to quit: 97
Enter grade or -1 to quit: 88
Enter grade or -1 to quit: 72
Enter grade or -1 to quit: -1
```

```
Total of the 3 grades entered is 257
Class average is 85.67
```

Type Cast (类型转换)

```
int total;          average = (double) total / gradeCounter;  
int gradeCounter;  
double average;
```

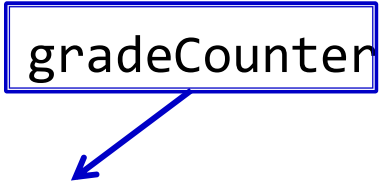

The unary cast operator creates a temporary floating-point copy of its operand

- ▶ Cast operator performs **explicit conversion** (or **type cast**). It has a higher precedence than the binary arithmetic operators (e.g., /).
- ▶ The value stored in the operand is unchanged (e.g., `total`'s value is not changed, `total`'s type is also not changed).

Type Promotion (类型提升)

```
int total;           average = (double) total / gradeCounter;  
int gradeCounter;  
double average;
```

Type promotion from **int** to **double**

A blue box highlights the variable 'gradeCounter' in the code. A blue arrow points from this box down to the word 'double' in the text 'Type promotion from int to double'.

- ▶ Java evaluates only arithmetic expressions in which the operands' types are identical.
- ▶ In the above expression, the **int** value of **gradeCounter** will be **promoted** (**implicit conversion**) to a **double** value for computation.

Why it is called promotion? **double** is more expressive

The Scope (作用域) of Variables

- ▶ Variables declared in a method body are **local variables** and can be used only from the line of their declaration to the closing right brace of the method declaration.
- ▶ A local variable's declaration must appear before the variable is used in that method

<https://www.geeksforgeeks.org/variable-scope-in-java/>

Is the code correct?

```
public class Scope {  
  
    public static void main(String[] args) {  
        int a = 3;  
    }  
  
    public static void foo() {  
        a = 3;   
    }  
}
```

a is a local variable in main, cannot be used outside main

Is the code correct?

```
public class Scope {
```

```
    public static void main(String[] args) {
```

```
        int a = 3;
```

```
        int a = 5; X
```

```
    }
```

a cannot be defined twice because the first a has a method-level scope

```
}
```

Is the code correct?

```
public static void main(String[] args) {  
    int a = 3;  
    b = a + 4;  b must be defined before use  
}
```

Block Scope (块作用域)

- ▶ A variable declared inside a pair of braces “{” and “}” in a method has a scope within the braces only

```
// generates a random number in [0, 1)
```

```
double a = Math.random();
```

```
System.out.println(a);
```

```
if(a > 0.5) {
```

```
    double b = 2 * a;
```

```
}
```

```
System.out.println(b);
```

b can be used only in the if block

Block Scope (块作用域)

- ▶ Due to the rule of variable scope, we often define counters before repetition statements

```
int counter = 0;
while(counter < 10) {
    // do something and increase counter
    // ...
    counter = counter + 1;
}
System.out.printf("repeated %d times\n", counter);
```

Compound Assignment Operators

(组合赋值操作符)

- ▶ Compound assignment operators simplify assignment expressions.
- ▶ *variable = variable operator expression;* where operator is one of +, -, *, / or % can be written in the form
*variable **operator**= expression;*
- ▶ `C = C + 3;` can be written as `C += 3;`

Compound Assignment Operators

Assignment operator	Sample expression	Explanation	Assigns
<i>Assume:</i> <code>int c = 3, d = 5, e = 4, f = 6, g = 12;</code>			
<code>+=</code>	<code>c += 7</code>	<code>c = c + 7</code>	10 to c
<code>-=</code>	<code>d -= 4</code>	<code>d = d - 4</code>	1 to d
<code>*=</code>	<code>e *= 5</code>	<code>e = e * 5</code>	20 to e
<code>/=</code>	<code>f /= 3</code>	<code>f = f / 3</code>	2 to f
<code>%=</code>	<code>g %= 9</code>	<code>g = g % 9</code>	3 to g

Increment and Decrement Operators

(自增、自减运算符)

- ▶ Unary **increment operator**, `++`, adds one to its operand
- ▶ Unary **decrement operator**, `--`, subtracts one from its operand
- ▶ An increment or decrement operator placed before a variable is called **prefix increment** or **prefix decrement operator** (前缀自增自减操作符).
- ▶ An increment or decrement operator placed after a variable is called **postfix increment** or **postfix decrement operator** (后缀自增自减操作符).

```
int a = 6;   int b = ++a;   int c = a--;
```

Preincrementing/Predecrementing

(前綴自增/自減)

- ▶ Using the prefix increment (or decrement) operator to add (or subtract) 1 from a variable is known as **preincrementing** (or **predecrementing**) the variable.
- ▶ Preincrementing (or predecrementing) a variable causes the variable to be incremented (decremented) by 1; then the new value is used in the expression in which it appears.

```
int a = 6;
```

```
int b = ++a; // b gets the value 7
```

Postincrementing/Postdecrementing

(后綴自增/自減)

- ▶ Using the postfix increment (or decrement) operator to add (or subtract) 1 from a variable is known as **postincrementing** (or **postdecrementing**) the variable.
- ▶ This causes the current value of the variable to be used in the expression in which it appears; then the variable's value is incremented (decremented) by 1.

```
int a = 6;
```

```
int b = a++; // b gets the value 6
```

Note the Difference

```
int a = 6;  
int b = a++; // b gets the value 6
```

```
int a = 6;  
int b = ++a; // b gets the value 7
```

```
int b = ++a;
```

Equivalent to:

```
a = a + 1;  
int b = a;
```

```
int b = a++;
```

Equivalent to:

```
int b = a;  
a = a + 1;
```

In both cases, a becomes 7 after execution, but b gets different values. Be careful when programming.

The Operators Introduced So Far

Precedence ↓	Operators						Associativity	Type
	++	--					right to left	unary postfix
	++	--	+	-	(type)		right to left	unary prefix
	*	/	%				left to right	multiplicative
	+	-					left to right	additive
	<	<=	>	>=			left to right	relational
	==	!=					left to right	equality
	?:						right to left	conditional
	=	+=	-=	*=	/=	%=	right to left	assignment

Please practice each of the operators by yourself ☺
